

Point-in-Polygon

Ray Trace
Method

Points outside Ω cross Ω_s
an even number of times

Points inside Ω cross Ω_s
an odd number of times

Class: Point

$\Rightarrow (x, y)$ coordinate

Class: Boundary

\Rightarrow a "list" of consecutive boundary points in clockwise order

Property: Edges

define 'edges' as tuples of 2 consecutive points

Method: Contains

Algorithm that inputs a point and outputs a boolean based on whether the point is within or without the boundary

Ray Trace Algorithm

1. Input a boundary, Ω_S , and a point P , per last page
2. Initialize boolean as 'false', indicating the point is outside of Ω_S
3. Starting from P , draw an infinite ray, R , pointing to the right.
4. Loop through all edges in Ω_S and **test** whether or not R intersects with them. Everytime it does, toggle the value of the boolean.
5. Return the boolean.

~ Test described in following ~
pages

Edge intersection algorithm

Given P , A , and B where A and B are the vertices of the edge where $A_y < B_y$:

Check if P is at the same height as A or B and move it if so.

IF $P_y == A_y$ or $P_y == B_y$:
 $P_y += \epsilon$

where ϵ is a small value.

Next, check if P is above, below, or to the right of the edge

IF $P_y > B_y$ or $P_y < A_y$ or $P_x > \max(A_x, B_x)$
Continue

Check if P is to the left of both A and B (now that the other options have been accounted for)

If $P_x < \min(A_x, B_x)$:
Toggle Balance
Continue

This only leaves the following rectangle for possible positions of P :

Calculate slope of \overline{AB} and \overline{AP}

If $m_{\overline{AP}} > m_{\overline{AB}}$, then P is in the green region and R intersects Ω_s , thus toggling the balance.
